A Fish Shell wrapper for Ian Bicking's virtualenv, somewhat loosely based on Doug Hellman's virtualenvwrapper for Bourne-compatible shells.

# Contents

# 1.1 Installation and Setup

#### 1.1.1 Installing

- 1. Make sure you're running Fish 2.x. If you're running an Ubuntu LTS release that has an older Fish version, install Fish 2.x via the fish-shell/release-2 PPA.
- 2. Install virtualfish by running pip install virtualfish.
- 3. Add the following to your ~/.config/fish/config.fish:

eval (python -m virtualfish)

If you want to use virtualfish with plugins, list the names of the plugins as arguments to the virtualfish loader:

eval (python -m virtualfish compat\_aliases)

*Note:* If your config.fish modifies your \$PATH, you should ensure that you load virtualfish *after* those modifications.

4. Customize your fish\_prompt

#### 1.1.2 Customizing Your fish\_prompt

virtualfish doesn't attempt to mess with your prompt. Since Fish's prompt is a function, it is both much less straightforward to change it automatically, and much more convenient to simply customize it manually to your liking.

The easiest way to add virtualenv to your prompt is to type funced fish\_prompt, add the following line in somewhere:

```
if set -q VIRTUAL_ENV
    echo -n -s (set_color -b blue white) "(" (basename "$VIRTUAL_ENV") ")" (set_color normal) " "
end
```

Then, type funcsave fish\_prompt to save your new prompt to disk.

# 1.2 Usage

#### 1.2.1 Commands

- vf new [<options>] <envname> Create a virtualenv. Note that <envname> must be last.
- vf ls List the available virtualenvs.
- vf activate <envname> Activate a virtualenv. (Note: Doesn't use the activate.fish script provided by virtualenv.)
- vf deactivate Deactivate the current virtualenv.
- vf rm <envname> Delete a virtualenv.
- vf tmp [<options>] Create a temporary virtualenv with a randomly generated name that will be removed when it is deactivated.
- vf cd Change directory to currently-activated virtualenv.
- vf cdpackages Change directory to the currently-activated virtualenv's site-packages.
- vf addpath Add a directory to this virtualenv's sys.path.
- vf all <command> Run a command in all virtualenvs sequentially.
- vf connect Connect the current working directory with the currently active virtualenv. This requires the *auto-activation plugin* to be enabled in order to have any effect besides creating a .venv file in the current directory.

If you're used to virtualenvwrapper's commands (workon, etc.), you may wish to enable the *Virtualenvwrapper Compatibility Aliases (compat\_aliases)* plugin.

### **1.2.2 Using Different Pythons**

By default, the environments you create with virtualenv (and, by extension, virtualfish) use the same Python version that virtualenv was installed under, which will usually be whatever your default system Python is.

If you want to use something different in a particular virtualenv, just pass in the --python PYTHON\_EXE (-p for brevity) argument to vf new, where PYTHON\_EXE is any Python executable, for example:

```
vf new -p python3 my_python3_env
vf new -p /usr/bin/pypy my_pypy_env
```

### 1.2.3 Configuration Variables

All of these must be set before virtual.fish is sourced in your ~/.config/fish/config.fish.

- VIRTUALFISH\_HOME (default: ~/.virtualenvs) where all your virtualenvs are kept.
- VIRTUALFISH\_DEFAULT\_PYTHON The default Python interpreter to use when creating a new virtualenv; the value should be a valid argument to virtualenv's --python flag.

# 1.3 Plugins

Virtualfish comes in-built with a number of plugins.

You can use them by passing their names in as arguments to the virtualfish loader in your config.fish, e.g.:

eval (python -m virtualfish auto\_activation global\_requirements)

#### 1.3.1 Virtualenvwrapper Compatibility Aliases (compat\_aliases)

This plugin provides some global commands to make virtualfish behave more like Doug Hellman's virtualenvwrapper.

#### Commands

- workon <envname> = vf activate <envname>
- deactivate = vf deactivate
- mkvirtualenv [<options>] <envname> = vf new [<options>] <envname>
- mktmpenv [<options>] = vf tmp [<options>]
- rmvirtualenv = vf rm <envname>
- lsvirtualenv = vf ls
- cdvirtualenv = vf cd
- cdsitepackages = vf cdpackages
- add2virtualenv = vf addpath
- allvirtualenv = vf all
- setvirtualenvproject = vf connect

#### 1.3.2 Auto-activation (auto\_activation)

With this plugin enabled, virtualfish can automatically activate a virtualenv when you are in a certain directory. To configure it to do so, change to the directory, activate the desired virtualenv, and run vf connect.

This will save the name of the virtualenv to the file .venv. Virtualfish will then look for this file every time you cd into the directory (or pushd, or anything else that modifies \$PWD).

Note: When this plugin is enabled, ensure any modifications to your \$PATH in your config.fish happen before virtualfish is loaded.

#### Commands

• vf connect - Connect the current virtualenv to the current directory, so that it is activated automatically as soon as you enter it (and deactivated as soon as you leave).

#### **Configuration Variables**

• VIRTUALFISH\_ACTIVATION\_FILE (default: .venv) - the name of the file virtualfish will use for the auto-activation feature. Earlier versions of virtualfish used .vfenv.

#### **State Variables**

• VF\_AUTO\_ACTIVATED - If the currently-activated virtualenv was activated automatically, set to the directory that triggered the activation. Otherwise unset.

### 1.3.3 Global Requirements (global\_requirements)

Keeps a global requirements.txt file that is applied to every existing and new virtualenv.

#### Commands

• vf requirements - Edit the global requirements file in your \$EDITOR. Applies the requirements to all virtualenvs on exit.

## 1.3.4 Projects (projects)

This plugin adds project management capabilities, including automatic directory switching upon virtual environment activation. Typically a project directory contains files — such as source code managed by a version control system — that are often stored separately from the virtual environment.

The following example will create a new project, with a matching virtual environment, both named YourProject:

vf project YourProject

The above command performs the following tasks:

- 1. creates new empty project directory in PROJECT\_HOME (if there is no existing YourProject directory within) and changes the current working directory to it
- 2. creates new virtual environment named YourProject and activates it

To work on an existing project, use the vf workon <name> command to activate the specified virtual environment and change the current working directory to the project of the same name. For cases in which the project name differs from the target virtualenv name, you can manually specify which virtualenv should be activated for a given project by creating a .venv file inside the project root containing the name of the corresponding virtualenv.

#### Commands

- vf project <name> Create a new project and matching virtual environment with the specified name. This name **must** be the last parameter (i.e., after -p python3 or any other arguments destined for the virtualenv command). If VIRTUALFISH\_COMPAT\_ALIASES is set, mkproject is aliased to this command.
- vf workon <name> Search for a project and/or virtualenv matching the specified name. If found, this activates the appropriate virtualenv and switches to the respective project directory. If VIRTUALFISH\_COMPAT\_ALIASES is set, workon is aliased to this command.
- vf lsprojects List projects available in \$PROJECT\_HOME (see below)
- vf cdproject Search for a project matching the name of the currently activated virtualenv. If found, this switches to the respective project directory. If VIRTUALFISH\_COMPAT\_ALIASES is set, cdproject is aliased to this command.

#### **Configuration Variables**

• PROJECT\_HOME (default: ~/projects/) - Where to create new projects and where to look for existing projects.

# **1.4 Extending Virtualfish**

#### 1.4.1 Variables

Virtualenv currently provides one global variable to allow you to inspect its state. (Keep in mind that more are provided by plugins.)

- VIRTUAL\_ENV Path to the currently active virtualenv.
  - Tips: use basename to get the virtualenv's name, or set -q to see whether a virtualenv is active at all.

### 1.4.2 Events

virtualfish emits Fish events instead of using hook scripts. To hook in to events that virtualfish emits, write a function like this:

```
function myfunc --on-event virtualenv_did_activate
    echo "The virtualenv" (basename $VIRTUAL_ENV) "was activated"
end
```

You can save your function by putting it in .config/fish/config.fish, or put it anywhere Fish will see it before it needs to run. (Note: saving it with funcsave won't work.)

Some events are emitted twice, once normally and once with the name of the virtualenv as part of the event name. This is to make it easier to listen for events relevant to one specific virtualenv, for example:

```
function myfunc --on-event virtualenv_did_activate:my_site_env
    set -gx DJANGO_SETTINGS_MODULE mysite.settings
end
```

The full list of events is:

- virtualenv\_did\_setup\_plugins
- virtualenv\_will\_activate
- virtualenv\_will\_activate:<env name>
- virtualenv\_did\_activate
- virtualenv\_did\_activate:<env name>
- virtualenv\_will\_deactivate
- virtualenv\_will\_deactivate:<env name>
- virtualenv\_did\_deactivate
- virtualenv\_did\_deactivate:<env name>
- virtualenv\_will\_create
- virtualenv\_did\_create
- virtualenv\_did\_create:<env name>

# **1.5 Frequently Asked Questions**

# 1.5.1 Why isn't Virtualfish written in Python?

Mostly, for the same reasons virtualenvwrapper is.

# 1.5.2 Does Virtualfish work with Python 3? What about PyPy?

**Yes!** In fact, you can create Python 3 virtualenvs even if your system Python is Python 2, or vice versa, using the --python argument (see the Usage section for full details).

## 1.5.3 Why does Virtualfish use Virtualenv and not pyvenv?

pyvenv may be the new shiny, but it can only be run from Python 3 and can only create Python 3 environments. In contrast, virtualenv fully supports Python 2 and 3, as discussed above. So, we can't use pyvenv on its own.

It's been suggested that we could use both, but that would add complexity for no real benefit. If pyvenv added new, broadly useful features not in virtualenv, or if virtualenv stopped working on Python 3, or if Python 2 went out of widespread use, this might change, but for now virtualenv is the best choice.

# 1.5.4 Why doesn't Virtualfish use activate.fish?

Virtualfish uses its own internal virtualenv activation code instead of the activate.fish file that comes with every virtualenv for two main reasons. One is that when Virtualfish was originally written, activate.fish didn't actually work. The second reason, which is still valid today, is that activate.fish tries to modify your fish\_prompt function.

Because fish\_prompt is a function and not a variable like in most other shells, modifying it programmatically is not trivial, and the way that virtualenv accomplishes it is more than a little hacky. The benefit of it being a function is that the syntax for customising it is much less terse and cryptic than, say, PS1 on Bash. This is why Virtualfish doesn't attempt to modify your prompt, and instead tells you how to do it yourself.

# 1.6 See Also

This page is for other projects that integrate with virtualfish, such as third-party plugins, prompts and so on. If you know of (or maintain!) such a project and it's not on this list, please file a pull request.

## 1.6.1 Prompts

• Both bobthefish and scorphish themes for Oh My Fish! support virtualfish.
